Introduction

The purpose of this document is to describe the ease of migration from an ARM7, ARM9 or ARM11 to the MIPS® architecture and cores.

MIPS Technologies supports the MIPS32® and MIPS64® instruction set architectures. MIPS64 allows 64-bit addressing modes to facilitate larger virtual address space. Migration from the MIPS32 to the MIPS64 architecture is a seamless path.

ARM is a 32-bit architecture . Beyond 32-bit and 64-bit, both MIPS and ARM supports 16 bit instructions for improved code density. Both architectures also support floating point.

Typically the application code running on these architectures is coded in a high level language such as C or C++, so porting between architectures is straightforward. MIPS provides a GNU tool chain that that can efficiently recompile the code to a MIPS platform. The extensive ecosystem for MIPS provides a variety of operating systems, software development tools and platforms from a broad range of vendors.

The bulk of the migration effort between architectures involves low-level boot code and device initialization. The areas that need special attention are: programming model, virtual to physical address mapping differences, cache and TLB initialization, differences in exception vectors and exception types and interrupt exceptions. For assembly code translation, the user needs to understand the differences in instruction set and register calling conventions.

This document is not meant to be an architecture reference manual nor a software users guide. The purpose of this document is to illustrate the differences in areas that need special attention by the user and also provides sample code segments for initialization of the resources.

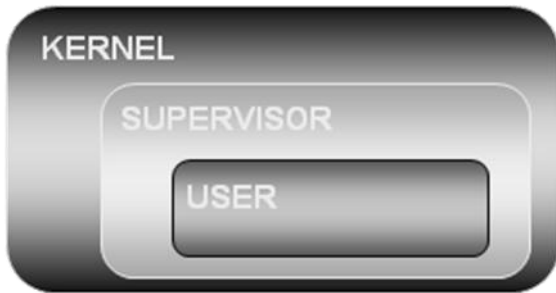

The user is encouraged to refer to the following documents for further reading and references:

MIPS32® Architecture for Programmers Volume I: Introduction to the MIPS32® Architecture
MIPS32® Architecture for Programmers Volume II: The MIPS32® Instruction Set
MIPS® Architecture for Programmers Volume III: The MIPS32® and microMIPS32™
Privileged Resource Architecture
YAMON™ Porting Requirements Specification
YAMON™ User's Manual

Details on tools and software, development kits, reference and users manuals and application notes can be found at mips.com.

Programming Model

MIPS Security Levels:

At the kernel level all processor resources are accessible. At the supervisor level all registers, supervisor segment and the 2GB user segment are accessible. At the user level the 2GB virtual address space is accessible. Typical usages are kernel and user modes. Supervisor mode is rarely used.

The kernel, supervisor and user state selection is made via the status register.

Mode	KSU	ERL	EXL
Kernel	x x	x	1
	x x	1	x
	0 0	x	x
Supervisor	0 1	0	0
User	1 0	0	0

ARM cores support 8 operating modes. FIQ, IRQ, Supervisor, System, Monitor, User, Undefined and Abort. Applications normally run in user mode.

MIPS handles interrupt exceptions, undefined instructions and memory access violations in the kernel mode.

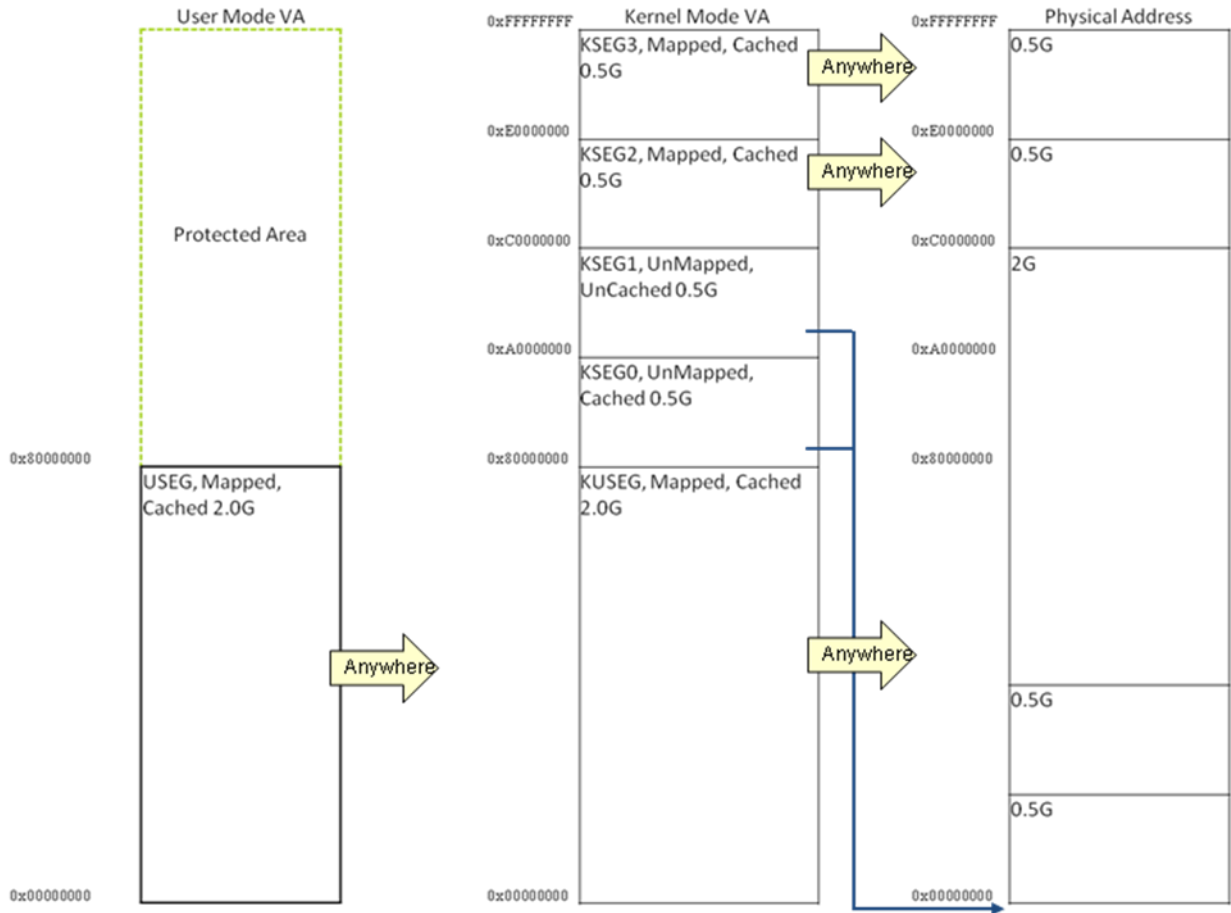

MIPS32 architecture specifies fixed memory map. The address space is divided into 4 regions:

- kseg2, TLB-mapped cacheable kernel space
- kseg1, direct-mapped uncached kernel space
- kseg0, direct-mapped cached kernel space
- kuseg, TLB-mapped cacheable user space

kseg0 and kseg1 segments are direct mapped and map to the first 512 megabytes of the physical address space. The rest of the regions are TLB-mapped and cacheable. Reset vector is 0xBFC00000 – kseg1. All exceptions default to kseg1 and can be relocated to kseg0 upon enabling of caches.

The ARM reset vector defaults to 0x00000000 or 0xFFFF0000 based on the SCTL.R.V bit. When the MMU is enabled the vector table can be located anywhere in the memory. The MMU and the MPU allow several different regions of memory with different protection and cache-ability attributes in ARM cores. Address space is flat and address translation takes place in mapped regions.

The following figure shows the virtual address to physical address mapping of the modes supported in MIPS cores:

Instruction set

Instruction sets for MIPS and ARM are similar. MIPS also supports application specific extensions (ASE) for DSP, security, multi-threading and other technologies. The CorExtend™ feature enables user defined instructions to be part of the core instructions set. All instruction in ARM can be conditionally executed based on ALU condition codes. MIPS provides conditional branches only. The MIPS ISA is fully backward-compatible and to some extent the ARM's architecture is also backward-compatible. The following table lists the classes of instructions that both architectures support.

	ARM1136JF-S™	MIPS32® 24Kc™
Add	ADD{cond}{S} <Rd>, <Rn>, <operand2>	ADD rd, rs, rt
Subtract	SUB{cond}{S} <Rd>, <Rn>, <operand2>	SUB rd, rs, rt
Multiply	MUL{cond}{S} <Rd>, <Rm>, <Rs>	MUL rd, rs, rt
Multiply-accumulate	MLA{cond}{S} <Rd>, <Rm>, <Rs>, <Rn>	MADD rs, rt
Count leading zeros	CLZ{cond} <Rd>, <Rm>	CLZ rd, rs

AND	AND{cond}{S} <Rd>, <Rn>, <operand2>	AND rd, rs, rt
XOR	EOR{cond}{S} <Rd>, <Rn>, <operand2>	XOR rd, rs, rt
OR	ORR{cond}{S} <Rd>, <Rn>, <operand2>	OR rd, rs, rt

Signed high 16 - low 16, low 16 + high 16, set GE flags	SSUBADDX{cond} <Rd>, <Rn>, <Rm>	SUBQ.PH rd,rs,rt
Saturated high 16 - low 16, low 16 + high 16	QSUBADDX{cond} <Rd>, <Rn>, <Rm>	SUBQ_S.PH rd,rs,rt
Four saturated unsigned 8 + 8	UQADD8{cond} <Rd>, <Rn>, <Rm>	ADDU_S.QB rd, rs, rt
Four saturated 8 - 8	QSUB8{cond} <Rd>, <Rn>, <Rm>	ADD_S.QB rd, rs, rt
Four saturated unsigned 8 - 8	UQSUB8{cond} <Rd>, <Rn>, <Rm>	SUBU_S.QB rd, rs, rt

CPU Initialization

The cache architecture for both the ARM and MIPS architectures are fairly similar: independent L1 for instruction and data and common a L2. MIPS caches are 1, 2 or 4 ways set associate and the line size is 4 or 8 words. Both architectures support write-back and write-thru options. Caches are disabled at reset.

The following code segments show cache operations for a MIPS32 24Kc core and the ARM1136JF-S:

Function	ARM1136JF-S™	MIPS32® 24Kc™
Enabling Cache	<pre>MRC p15, 0, r0, c1, c0, 0 ; read CP15 register 1 into r0 ORR r0, r0, #(0x1 <<12) ; enable I Cache ORR r0, r0, #(0x1 <<2) ; enable D Cache MCR p15, 0, r0, c1, c0, 0 ; write CP15 register 1</pre>	<pre>mfc0 t0, C0_Config1 /* set kseg0 as Cacheable, noncoherent, write-back, write allocate */ ori t0,t0, 0x3 mtc0 t0, C0_Config1</pre>

Function	ARM1136JF-S™	MIPS32® 24Kc™
Invalidate Cache	<pre>MRC p15,0,R0,c0,c0,1 ; Read cache type reg AND R0,R0,#0x1C0000 ; Extract D cache size MOV R0,R0,LSR #18 ; Move to bottom bits ADD R0,R0,#7 ; Get Index loop max MOV R1,#3:SHL:30 ; Set up Set = 3 MOV R2,#0 ; Set up Index counter MOV R3,#1 MOV R3,R3,LSL R0 ; Set up Index loop max index_loop ORR R4,R2,R1 ; Way and Set format MCR p15,0,R4,c7,c14,2 ; Clean&inval D cache line ADD R2,R2,#1:SHL:5 ; Increment Index CMP R2,R3 ; Done all index values? BNE index_loop ; Loop until done</pre>	<pre>mfc0 a1, C0_Config1 and a1, M_Config1IL srl a1, S_Config1IL li v0, 0x2 sll v0, a1 /* a1 = I-cache line size */ mfc0 t9, C0_Config1 and t8, t9, M_Config1IA srl t8, S_Config1IA addiu t8, 1 /* t8 = associativity */ and t9, M_Config1IS srl t9, S_Config1IS li t7, 0x40 sll t7, t9 /* t7 = sets per way */ multu t8, t7 mflo a0 /* a0=cache size */ MTC0(zero, C0_TagHi) MTC0(zero, C0_TagLo) 0: li a2, KSEG0BASE /* Calc 1st cache line address*/ addu a3, a2, a0 /* Calc last cache line address*/ subu a3, a1 1: /* Loop through all lines, invalidating each of them */ cache ICACHE_INDEX_STORE_TAG, 0(a2) /* clear tag */ bne a2, a3, 1b addu a2, a1</pre>

TLB initialization:

Both the ARM and MIPS architectures support virtual-to-physical address translation via TLB scheme. Page sizes ranging from 4KB to 256MB are supported by both architectures. In the MIPS architecture, on a TLB miss, a system exception is raised and an exception handler loads the appropriate configuration in the TLB. In the ARM architecture, TLB misses are handled in hardware by a two-level page table walk mechanism. MIPS also supports a couple of simpler schemes - Fixed address translation and Block address translation. ARM supports such schemes via the Memory Protection Unit (MPU).

The following code segment shows TLB initialization:

Function	ARM1136JF-S™	MIPS32® 24Kc™
Initialize TLB Entry	- N/A	<pre> void initTLBEntryByIndex (int idx) { int i; __asm__ __volatile ("move \$t0, %0" :: "r" (idx)); __asm__ __volatile ("mtc0 \$t0, \$0, 0;" // set index "lui \$t1, 0xa000;" "sll \$t0, \$t0, 16;" "or \$t1, \$t0,\$t1;" "mtc0 \$t1, \$10,0;" //entryhi "mtc0 \$zero, \$2,0;" //entrylo0 "mtc0 \$zero, \$3,0;" //entrylo1 "mtc0 \$zero, \$5,0;" //pagemask "tlbwi;" "ehb;"); return; } </pre>

Exception vector and exception type

The following table is a summary of the exception vector and types for the MIPS and ARM architectures:

ARM1136JF-S™	MIPS32® 24Kc™
Support 7 different types/priorities of exceptions	Support 35 different types/priorities of exceptions: offering the programmer more knowledge of what went wrong and allowing the user to handle it differently
Exception base is predefined to 0x0000.0000 and 0xFFFF.0000	Exception base is predefined to 0xBFC0.0000 and 0x8000.0000
	Exception base can be changed by EBase

The following tables list the details of exception vector, exception types and priorities for the ARM and MIPS architectures:

ARM Exception vector address(V=0, V=1)	Mode on entry	MIPS Exception vector address (SI_UseExceptionBase, Status.BEV, Status.EXL, Cause.IV, EJTAG ProbEn)	Exception Types
0x0000.0000, 0xFFFF.0000	Supervisor	16#BFC0.0000	Reset, NMI
0x0000.0004, 0xFFFF.0004	Undefined	16#BFC0.0200	Other, TLB Refill
0x0000.0008, 0xFFFF.0008	Supervisor	16#BFC0.0300	Cache Error
0x0000.000C, 0xFFFF.000C	Prefetch Abort	16#BFC0.0380	TLB Refill, Interrupt, All Others
0x0000.0010, 0xFFFF.0010	Data Abort	16#BFC0.0400	Interrupt
0x0000.0014, 0xFFFF.0014	Reserved	16#BFC0.0480	EJTAG Debug
0x0000.0018, 0xFFFF.0018	IRQ	16#8000.0180	TLB Refill, Interrupt, All Others
0x0000.001C, 0xFFFF.001C	FIQ	16#8000.0280	Interrupt
		16#A000.0100	Cache Error
		16#FF20.0200	EJTAG Debug

ARM1136JF-S™		MIPS32® 24Kc™		
Priority	Name	Priority	Name	Description
1	Reset (highest priority).	1	Reset	Assertion of SI_Reset signal
		2	DSS	EJTAG Debug Single Step
		3	DINT	EJTAG Debug Interrupt.; caused by the assertion of the external EJ_DINT input, or by setting the EhtagBrk bit in the ECR register
		4	DDBLImpr/DDBSImpr	Debug Data Break Load/Store Imprecise
		5	NMI	Asserting edge of SI_NMI signal
2	Precise Data Abort.	6	Machine Check	TLB write that conflicts with an existing entry
3	FIQ.	7	Interrupt	Assertion of unmasked hardware or software interrupt signal
4	IRQ.			
7	SWI (lowest priority)			
		8	Deferred Watch	Deferred Watch (unmasked by K DM->!(K DM) transition)
		9	DIB	EJTAG debug hardware instruction break matched

ARM to MIPS® Architecture Migration Guide

			10	WATCH	A reference to an address in one of the watch registers (fetch)
6	Prefetch Abort.		11	AdEL	Fetch address alignment error; fetch reference to protected address.
2	Precise Data Abort.		12	TLBL	Fetch TLB miss; fetch TLB hit to page with V=0
			13	ICache Error	Parity error on ICache access
5	Imprecise Data Aborts.		14	IBE	Instruction fetch bus error
			15	DBp	EJTAG Breakpoint (execution of SDBBP instruction)
			16	Sys	Execution of SYSCALL instruction
7	BKPT		17	Bp	Execution of BREAK instruction
			18	CpU	Execution of a coprocessor instruction for a coprocessor that is not enabled
			19	CEU	Execution of a CorExtend instruction modifying local state when CorExtend is not enabled
7	Undefined instruction		20	RI	Execution of a Reserved Instruction
			21	FPE	Floating Point exception
			22	C2E	Coprocessor2 Exception
			23	IS1	Implementation specific Coprocessor2 exception
			24	Ov	Execution of an arithmetic instruction that overflowed
			25	Tr	Execution of a trap (when trap condition is true)
			26	DDBL / DDBS	EJTAG Data Address Break (address only)
			27	WATCH	A reference to an address in one of the watch registers (data)
2	Precise Data Abort.		28	AdEL	Load address alignment

				error. Load reference to protected address
2	Precise Data Abort.	29	AdES	Store address alignment error. Store to protected address
2	Precise Data Abort.	30	TLBL	Load TLB miss. Load TLB hit to page with V=0
2	Precise Data Abort.	31	TLBS	Store TLB miss. Store TLB hit to page with V=0
2	Precise Data Abort.	32	TLB Mod	Store to TLB page with D=0
5	Imprecise Data Aborts.	33	DCache Error	Cache parity error - imprecise
5	Imprecise Data Aborts.	34	L2 Cache Error	L2 Cache ECC error - imprecise
5	Imprecise Data Aborts.	35	DBE	Load or store bus error - imprecise

Interrupt exception

The MIPS and ARM architectures have similar interrupt schemes. The MIPS architecture has an integrated interrupt controller that supports up to 6 priorities in VI mode and up to 63 priorities in EIC mode. The ARM architecture requires an external interrupt controller to support VI mode. External interrupts are mapped to FIQ and IRQ; hence faster response times on the MIPS architecture. The MIPS architecture also has a cause register that reflects the cause of the interrupt. The following table summarizes the interrupt schemes for each architecture:

ARM1136JF-S™	MIPS32® 24Kc™
Two types FIQ and IRQ	One type but 3 operating modes (Compatibility, VI, EIC)
Bank registers for supporting better interrupt response	Shadow register for better interrupt service response
Maximum 16 active registers can be used	Maximum 32 active registers can be used
Need to handshake with external interrupt controller to get effective vector address	Has faster interrupt response time (CPU will calculate the vector address)

The following table details the interrupt exceptions for ARM and MIPS.

ARMv5	MIPS32® 24Kc™
-------	---------------

Exception Address	FIQhandler	Exception Address	Interrupt Handler
0x0000.001C	LDR PC, [R8,#HandlerAddress] ...	0x8000.02A0	Interrupt Handler 1 ... Include code to process the interrupt ERET
#Handler Addr1	FIQ1handler ... Include code to process the interrupt STR R0, [R8,#AckFinished] SUBS PC, R14, #4 ...	0x8000.02C0	Interrupt Handler 2 ... Include code to process the interrupt ERET
#Handler Addr2	FIQ2handler ... Include code to process the interrupt STR R0, [R8,#AckFinished] SUBS PC, R14, #4 ...	0x8000.02E0	Interrupt Handler 3 ... Include code to process the interrupt ERET
Exception Address	FIQhandler	Exception Address	Interrupt Handler
#Handler Addr1	FIQ1handler ... Include code to process the interrupt STR R0, [R8,#AckFinished] SUBS PC, R14, #4 ...	0x8000.02A0	Interrupt Handler 1 ... Include code to process the interrupt ERET
#Handler Addr2	FIQ2handler ... Include code to process the interrupt STR R0, [R8,#AckFinished] SUBS PC, R14, #4 ...	0x8000.02C0	Interrupt Handler 2 ... Include code to process the interrupt ERET
#Handler Addr3	FIQ2handler ... Include code to process the interrupt STR R0, [R8,#AckFinished] SUBS PC, R14, #4 ...	0x8000.02E0	Interrupt Handler 3 ... Include code to process the interrupt ERET

Application Binary Interface (ABI)

When coding in assembly, the ARM architecture provides 6 active registers (vx) for arithmetic and load store operations. The MIPS architecture provides 18 active registers (tx + sx). The MIPS architecture provides 32 general purpose registers, while ARM has only 16 active registers. A larger register set eases register pressure for compiled code.

The following table shows the register calling convention for ARM and MIPS:

Number	Name	Purpose	Number	Name	Purpose
			\$0	\$0	Always 0
			\$1	\$at	The Assembler Temporary used by the assembler in expanding pseudo-ops.
r12	Ip	Intra-procedure-call scratch register	\$2-\$3	\$v0-\$v1	These registers contain the Returned Value of a subroutine; if the value is 1 word only \$v0 is significant.
r0-r3	a1-a4	Argument, result, or scratch registers	\$4-\$7	\$a0-\$a3	The Argument registers, these registers contain the first 4 argument values for a subroutine call.
r4-r11	v1-v8	Variable registers	\$8-\$15, \$24,\$25	\$t0-\$t9	The Temporary Registers.
			\$16-\$23	\$s0-\$s7	The Saved Registers.
			\$26-\$27	\$k0-\$k1	The Kernel Reserved registers. DO NOT USE.
r9	sb	Static base	\$28	\$gp	The Global Pointer used for addressing static global variables. For now, ignore this.
r13	sp	Stack pointer	\$29	\$sp	The Stack Pointer.
r11	fp	Frame pointer	\$30	\$fp (or \$s8)	The Frame Pointer: programs that do not use an explicit frame pointer (e.g., everything assigned in ECE314) can use register \$30 as another saved register – not recommended however
r14	lr	Link register	\$31	\$ra	The Return Address in a subroutine call
r15	pc	Program counter			

Migrating applications

Reset, initialization and exception handling are typically done in assembly, but it is common that the application itself is coded in C/C++ (high level language). The application and any device drivers must be recompiled with the MIPS tool chain. Any assembly code can be translated manually, as there is almost a one-to-one equivalent instruction.

The bulk of the effort in migration entails changes to the initialization and low level boot code. MIPS Technologies provides the YAMON™ PROM monitor as reference code that runs on MIPS development boards. There are boot loaders available from third party vendors and open source.

On both the ARM and MIPS architectures, applications normally will run in user mode. On an exception, ARM will switch to Supervisor mode and MIPS will enter the kernel mode. The exception handler switches the mode back to user mode upon handling the exception. On ARM stacks and stack pointers for each mode need to be initialized. Only the kernel stack needs to be initialized on MIPS. Exceptions save context in reserved memory space.

Memory map on the MIPS architecture is fixed and user space is kuseg segment of the memory. Kseg0-3 is reserved for kernel. Cached system data resides in kseg0 and uncached in kseg1. ARM allows the system data and user code to be mapped to anywhere in the valid address range. I/O devices in the MIPS architecture are mapped in kseg1 and anywhere in valid memory range on the ARM architecture.

In both ARM and MIPS most of the exception handling is done in software. ARM supports two external interrupt handlers, namely FIQ and IRQ. FIQ is normally used for low latency interrupts and has a higher priority. Nested interrupts are typically handled by IRQ through a 2 -stage interrupt handler. The nested IRQ handler must save the registers on the system stack before enabling the interrupts, in order to prevent corruption of the return address.

MIPS supports six external interrupts, and each can be masked independently. Nested interrupts are handled in a similar fashion. Exception context must be saved before re-enabling the interrupts. Configuring interrupts is straightforward in the MIPS architecture. Only the status register fields must be programmed.

The MIPS ISA defines both MIPS32 and MIPS64. MIPS64 offers larger virtual address and physical address space, and MIPS32 applications can be seamlessly migrated to MIPS64 to take advantage of the 64-bit pointers. Long word is 128 bits in MIPS64 and in both MIPS32 and MIPS64, char is 8-bit unsigned. MIPS provides N32 and N64 ABIs for embedding assembly code with C/C++.

MIPS Technologies offers the MIPS Navigator™ Integrated Component Suite (ICS) that comes with a GNU compiler and debugger, JTAG level debugger, profiler and event analyzer. Several other software vendors also provide tool suite for MIPS processors.

Summary

MIPS Technologies licenses its MIPS32 and MIPS64 architectures, and also offers single-core, multi-core, superscalar and multi-threaded families of cores based on the MIPS32 architecture. Several of MIPS Technologies' licensees also offer high-performance, multicore products based on the MIPS64 architecture.

With its architectures and cores, MIPS has a large footprint in digital home and networking applications, and growing traction in mobile devices.

MIPS cores are the industry's most area efficient, offering high performance at the lowest power dissipation. With its multi-threading technology, companies can efficiently implement a parallelizable application by maximizing the instructions per cycle (IPC). The QoS features in the multi-threaded family of products help ensure real-time application performance. The breadth and the rich features of MIPS' product portfolio, coupled with a flexible business model, enable MIPS licensees to create MIPS-Based products that range from 32-bit microcontrollers and energy efficient mobile devices to 'green' supercomputers and high end networking infrastructure.
